Optimized diagnosis and treatment management of patients infected with HCV

Patient management relies on accurate diagnosis

Diagnosis and management of HCV require a combination of tests

Hepatitis C virus (HCV) infection and its clinical stages are diagnosed using a combination of tests for markers of HCV.

- HCV antibodies (anti-HCV) as first line test to screen for and diagnose infection with HCV
- HCV RNA to confirm active infection with HCV and to monitor HCV viral load before, during and after anti-viral therapy
- HCV genotyping to determine the HCV genotype and subtype to select an appropriate treatment regimen¹

The measure of Alanine aminotransferase (ALT) is a supportive aid in the diagnosis of hepatic diseases and for screening of liver damage^{1,2}

Roche offers the cobas® system family of diagnostic platforms to run the key tests for the diagnosis of HCV infection and management of chronic hepatitis C.

Hepatitis C virus diagnostic pathway

Figure 1: Key steps in the diagnosis and management of HCV infection

Elecsys[®] Anti-HCV II assay for accurate diagnosis of HCV Reliable and consistent results for patient-oriented decision making

HCV infection can be detected by measuring the amount of HCV RNA using Polymerase Chain Reaction (PCR), alanine aminotransferase (ALT) and HCV-specific immunoglobulins (anti-HCV) in patient serum samples. This can also indicate if the infection is acute or chronic1.

Figure 2: Course of markers during acute HCV infection

Confirmatory HCV RNA testing

Sensitive detection of active infection for effective patient management

HCV RNA detection is vital for optimal patient management

HCV antibody screening can yield positive results in patients who were infected with HCV but who subsequently cleared infection. Therefore, specific testing for HCV RNA is required in order to determine HCV infection status and to confirm the infection³. The measure of HCV RNA can also be used in the window period between exposure and seroconversion.

Table 1: Interpretation of assay results for HCV

HCV infection status	Anti-HCV	HCV RNA
No HCV infection	_	
Resolved HCV infection	+	
Active HCV infection	+	+
Acute HCV infection or chronic infection in conditions which may suppress antibody	_	+

Detection of HCV RNA by PCR offers a highly sensitive and specific means of detecting active viremia which is associated with chronic HCV infection. The combination of HCV antibody and HCV RNA testing can be used to accurately classify HCV disease status.

Figure 4: CDC recommended testing sequence to identify current infection⁴

** For persons who might have been exposed to HCV within the past 6 months, testing for HCV RNA or follow-up testing for HCV antibody is recommended. For persons who are immunocompromised, testing for HCV RNA can be considered.

¹ To differentiate past, resolved HCV infection from biologic false positivity for HCV antibody, testing with another HCV antibody assay can be considered. Repeat HCV RNA testing if the person tested is suspected to have had HCV exposure within the past 6 months or has clinical evidence of HCV disease, or if there is concern regarding the handling or storage of the test specimen.

Identifying HCV genotype *Making the right choice of therapy*

HCV genotyping is essential for chronic hepatitis C treatment decisions

HCV genotype has been one of the strongest baseline predictors for achieving sustained virological response (SVR), with the old Standard of Care, pegylated-interferon a (pIFN) in combination with ribavirin (RBV). For the new therapies based on direct acting antivirals (DAAs), antiviral efficacy is genotype or genotype 1 subtype (a/b) selective, and the genotype in combination with other factors, like treatment experience and liver status, guides the physician to determine the right combination of antiviral drugs and treatment duration.5

Determination of HCV genotype, on which the regimen, dosing, and duration of therapy as well as likelihood of response depends, is thus essential to making decisions about treatment.

Table 2: Treatment duration (in weeks) for non-cirrhotic patients according to EASL guidelines 2015⁶

genotype	SOF/P/R	SMV/P/R	SOF/R	SOF/LPV	PTVr/ OBV/DBV	PTVr/OBV	SOF/SMV	SOF/DCV

The value of HCV RNA testing

A critical assessment tool in the age of direct-acting antivirals

Effectively manage HCV treatment with quantitative HCV RNA testing

To achieve an optimal treatment outcome, regular HCV viral load assessment should be utilized to guide therapy decisions. A quantitative HCV RNA test allows to:

- Assess viral suppression in response to therapy •
- Identify adherence or non-compliance
- Detect treatment non-responders
- Differentiate viral breakthrough from relapse at end of treatment
- Determine treatment futility (simeprevir triple therapy only)
- Determine treatment duration based on the HCV RNA baseline level (sofosbuvir/ledipasvir combination therapy)

Monitoring of treatment efficacy is based on repeated measurements of HCV RNA levels using a sensitive (limit of detection ≤15 IU/mL), accurate assay with a broad dynamic range of quantification. Using such an assay, the endpoint of therapy (sustained virologic response, SVR) is defined as undetectable HCV RNA 12 or 24 weeks after end of treatment^{5.6}.

Table 4: Recommended viral load testing points according to EASL guidelines 2015⁵

	Baseline	Week 2	Week 4	Week 12	ΕΟΤ	SVR
sofosbuvir + IFN + RBV			۲		۲	۲
simeprevir + IFN + RBV			۲		۲	۲
IFN-free regimens		۲	۲		۲	۲

Elecsys® serological assays for accurate diagnosis of HBV

Reliable and consistent results for patient-oriented decision making

The natural history of hepatitis B virus (HBV) infection is complex and variable and is greatly influenced by the age at infection, the level of HBV replication, and host immune status¹⁰. Diagnosis of the presence and stage of HBV infection is achieved by measuring the serum markers discussed above.

Figure 6: Typical course of acute hepatitis B infection with recovery¹¹

Figure 7: Typical course of a hepatitis B virus infection with progression to chronic hepatitis B11

HBsAg and Anti-HBs are the core tests for screening and diagnosis of HBV infection

Screening is recommended in all patients who are at increased risk of contracting HBV, especially those from HBV-endemic regions of the world (HBV prevalence $\geq 2\%$). Current guidelines specify the groups that should be routinely screened for HBV infection^{12,13}.

Figure 8: HBV Screening Algorithm for at risk patients^{12,13}

The value of HBV DNA testing *A critical assessment tool for long term patient monitoring*

The natural course of chronic HBV infection consists of 4 phases; determined by serum levels of alanine aminotransferase (ALT), Hepatitis B virus (HBV) DNA levels, and the presence or absence of hepatitis B e antigen (HBeAg)^{10,11}.

Measurement of HBV levels is the standard tool for the clinical management of chronic HBV to establish a baseline prior to treatment, monitor antiviral response during treatment and survey virological breakthrough. Serum HBV DNA level is an important and independent risk factor for disease progression in chronic hepatitis B.

HBV DNA levels can fluctuate markedly during the course of chronic HBV infection. The natural course of the disease is highly dynamic and not every patient requires therapy¹⁷.

Figure 10: HBV Evaluation and Monitoring Algorithm^{14,15,16}

The four stages of chronic Hepatitis B

The value of HBsAg quantification

An additional marker to assist in patient management

Combination of HBsAg levels with serum HBV DNA levels is valuable in the following scenarios¹⁸.

Identifying inactive carriers and assessing risk for disease progression for Hepatocellular carcinoma (HCC):

A number of independent studies and the current recommendations for the American and European guidelines have shown that the combination of HBV DNA < 2000 IU/mL and HBsAg < 1000 IU/mL can reliably identify inactive carriers^{20,21,22}.

They are at low risk of disease progression and with appropriate management have an excellent chance of achieving hepatitis B surface antigen (HBsAg) clearance, closest outcome to a clinical cure.

The HBsAg level ≥ 1000 IU/mL identified as a new independent risk factor in patients with HBV DNA < 2000 IU/mL¹⁹.

Figure 11: Inactive carrier identification

Under current clinical practive guidelines, these patients would not be considered for therapy.

Response-guided therapy in peg-interferon alfa-2a monitoring: Help to identify if patients are responding to therapy and if they are on track to achieving sustained immune control.

Figure 12: Practical application of response-guided therapy during PEG-IFN-a treatment using HBsAg levels²³ *Response in HBeAg positive patients defined as HBeAg seroconversion 6 months post-treatment. Response in HBeAg negative patients defined as HBV DNA ≤10,000 copies/mL 1 year post-treatment.

HBV and HCV diagnostic and monitoring tests from Roche offer clinically relevant performance

Roche offers different quantitative HCV RNA and HBV DNA tests for its family of diagnostic platforms that fulfills the sensitivity requirements for monitoring and aiding in clinical management. These tests provide robust, clinically relevant assay performance with a broad linear range and high sensitivity and deliver optimal results throughout critical medical decision points and across all genotypes. All tests offer an optimised and fully automated workflow to maximize laboratory efficiency.
